KogovÅjek et al.: Jellyfish biochemical composition several methods commonly used in zooplankton ecology as well as to determine jellyfish biomass, elemental, stable isotope and amino acid pool composition were compared and assessed. We introduce a new desalination method into jellyfish sample processing.

## **Jellyfish biochemical composition: importance of**

The significant levels of 20:4w6 in jellyfish total lipid (9.7%–20.0% of the total fatty acids) and in the leatherback neutral lipid (1.0%–10.9% of the total fatty acids) and phospholipid (0.6%–15.5% of total fatty acids) fractions of all tissues sampled suggests that arachidonic acid assumes more importance in food chain relationships involving leatherbacks than in other marine food webs such as those involving fish.

Tentacles armed with stinging cells (cnidocytes) are a defining trait of the cnidarians, a phylum that includes sea anemones, corals, jellyfish, and hydras. While cnidarian tentacles are generally characterized as structures evolved for feeding and defense, significant variation exists between the tentacles of different species, and within the same species across different life stages and/or body regions.

Semi-dried jellyfish represent a multi-million dollar seafood business in Asia. Traditional processing methods involve a multi-phase processing procedure using a mixture of salt (NaCl) and alum ( $AlK[SO_4]_2 \cdot 12 H_2 O$ ) to reduce the water content, decrease the pH, and firm the texture. Processed jellyfish have a special crunchy and crispy texture.
